

FP-Tree

T-61.6020: Popular Algorithms
in Data Mining and
Machine Learning

Outline

- Problem description
- Motivation for the FP-Tree algorithm
- The FP-Tree algorithm

Problem description

- Transaction database
 - Transactions consist of a set of items $I = \{a, b, c, \dots\}$

| TID | Items Bought |
|-----|------------------------|
| 1 | f, a, c, d, g, i, m, p |
| 2 | a, b, c, f, l, m, o |
| 3 | b, f, h, j, o |
| 4 | b, c, k, s, p |
| 5 | a, f, c, e, l, p, m, n |

Problem description

- What products are often bought together?
 - (digital camera, memory card, extra battery)
- Problem: Find frequent item sets
 - $frequency \geq minimum\ support\ threshold$
 - Same problem as Apriori

Apriori reminder

- <http://www.cs.ualberta.ca/~zaiane/courses/cmput499/slides/Lect10/sld054.htm>

Why FP-Tree and not Apriori?

- Apriori works well except when:
 - Lots of frequent patterns
 - Big set of items
 - Low minimum support threshold
 - Long patterns
- Why: Candidate sets become huge
 - 10^4 frequent patterns of length 1 → 10^7 length 2 candidates
 - Discovering pattern of length 100 requires at least 2^{100} candidates (nr of subsets)
 - Repeated database scans costly (long patterns)

FP-Tree: Ideas

- Avoid candidate set explosion by:
 - 1) Compact tree data structure
 - Avoid repeated database scans
 - 2) Restricted test-only
 - Apriori: restricted generation-and-test
 - 3) Search divide-and-conquer based
 - Apriori: bottom-up construction

FP-Tree: Algorithm

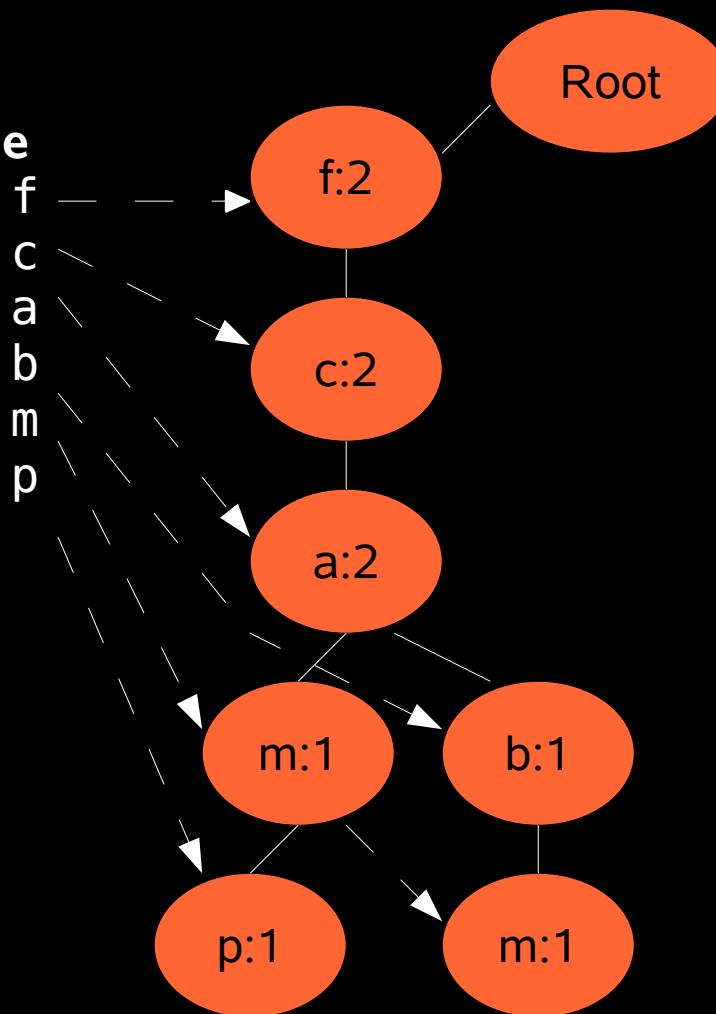

- Order all items in itemset in frequency descending order (min support = 3)

| TID | Items Bought | (Ordered) Frequent Items |
|-----|------------------------|--------------------------|
| 1 | f, a, c, d, g, i, m, p | f, c, a, m, p |
| 2 | a, b, c, f, l, m, o | f, c, a, b, m |
| 3 | b, f, h, j, o | f, b |
| 4 | b, c, k, s, p | c, b, p |
| 5 | a, f, c, e, l, p, m, n | f, c, a, m, p |

(f:4, c:4, a:3, b:3, m:3, p:3)

FP-Tree: Data Structure

Header table

- Paths represent transactions
- Nodes have counts to track original frequency

FP-Tree: Construction

- `insert_tree([p|P], T)`
 - If T has a child n, where n.item = p increment n.count by one
 - else create new node N with n.count = 1
 - Link it up from the header table
- If P is nonempty call `insert_tree(P, N)`

FP-Tree: Construction

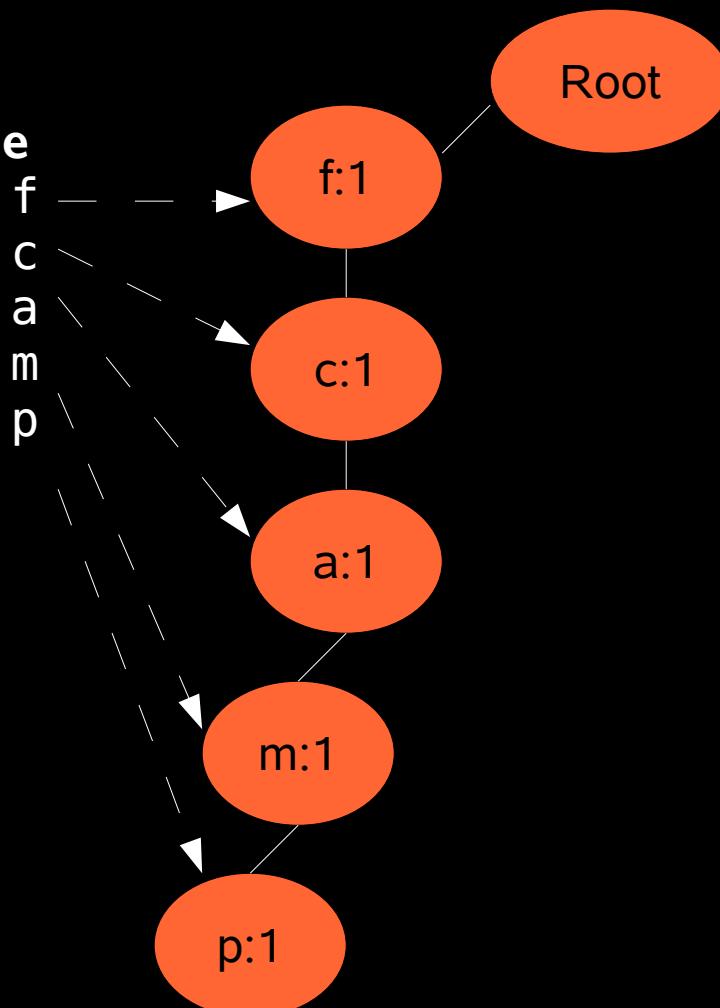

- Originally empty

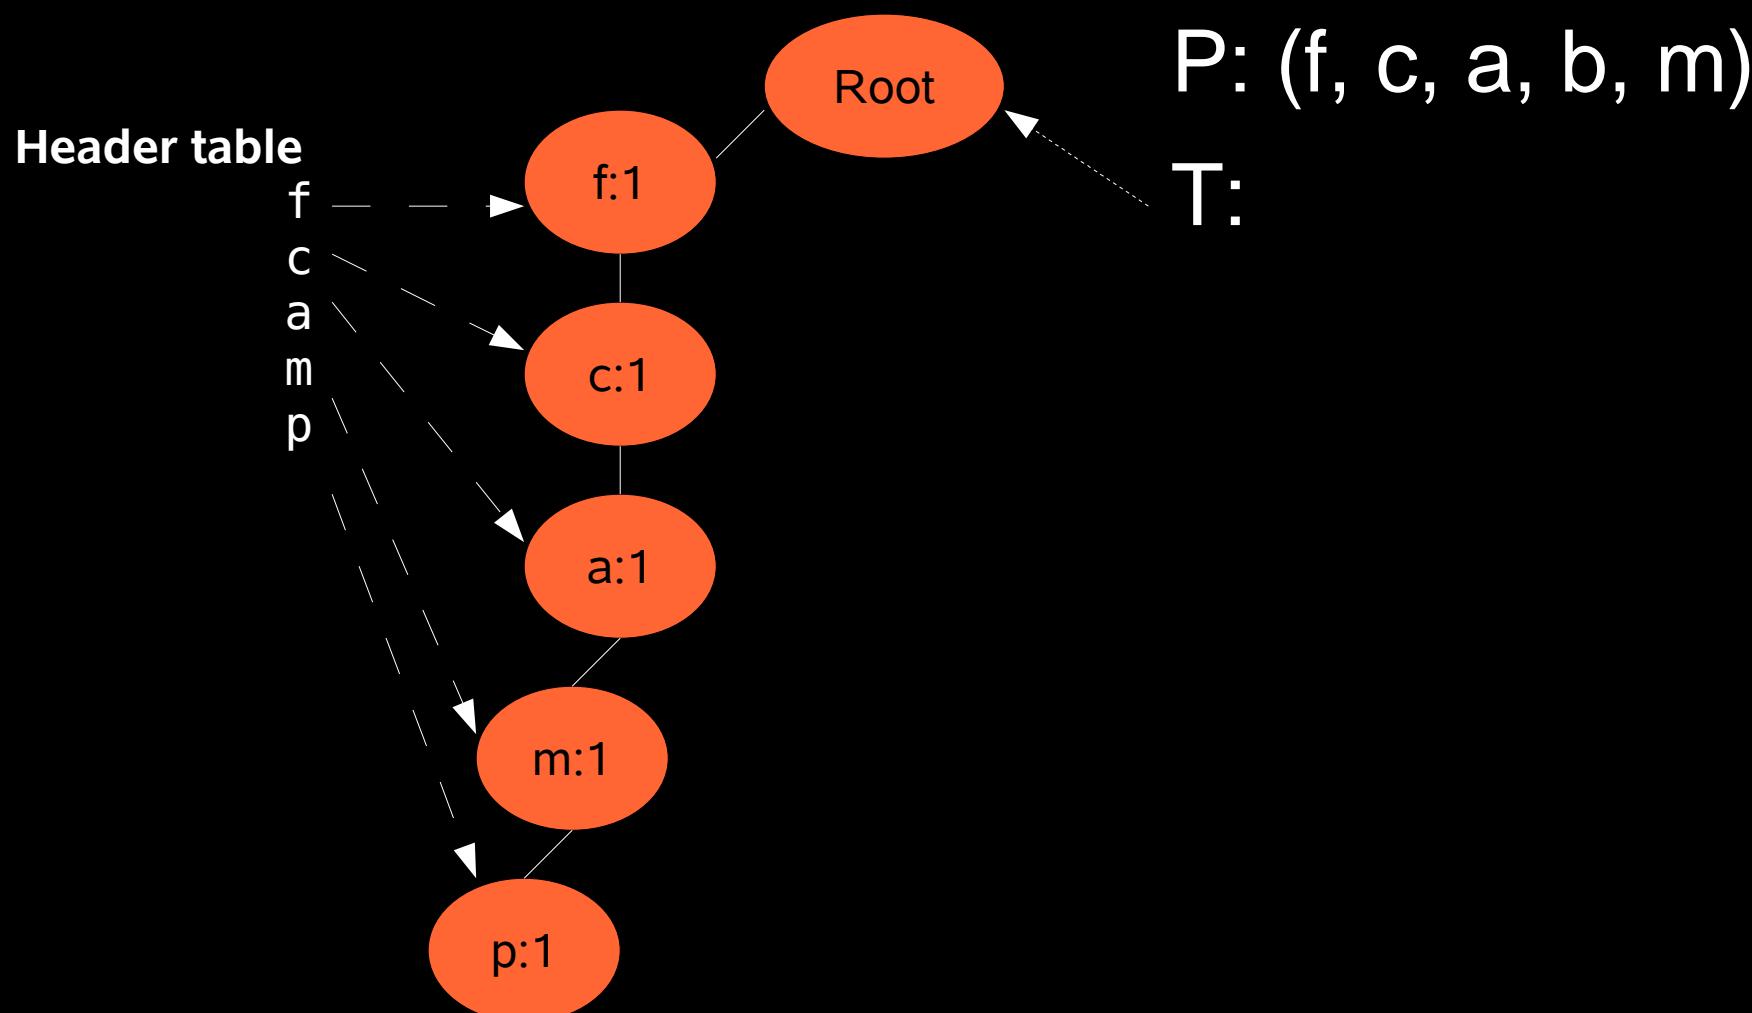

FP-Tree: Construction

- After inserting first transaction (f, c, a, m, p)

Header table

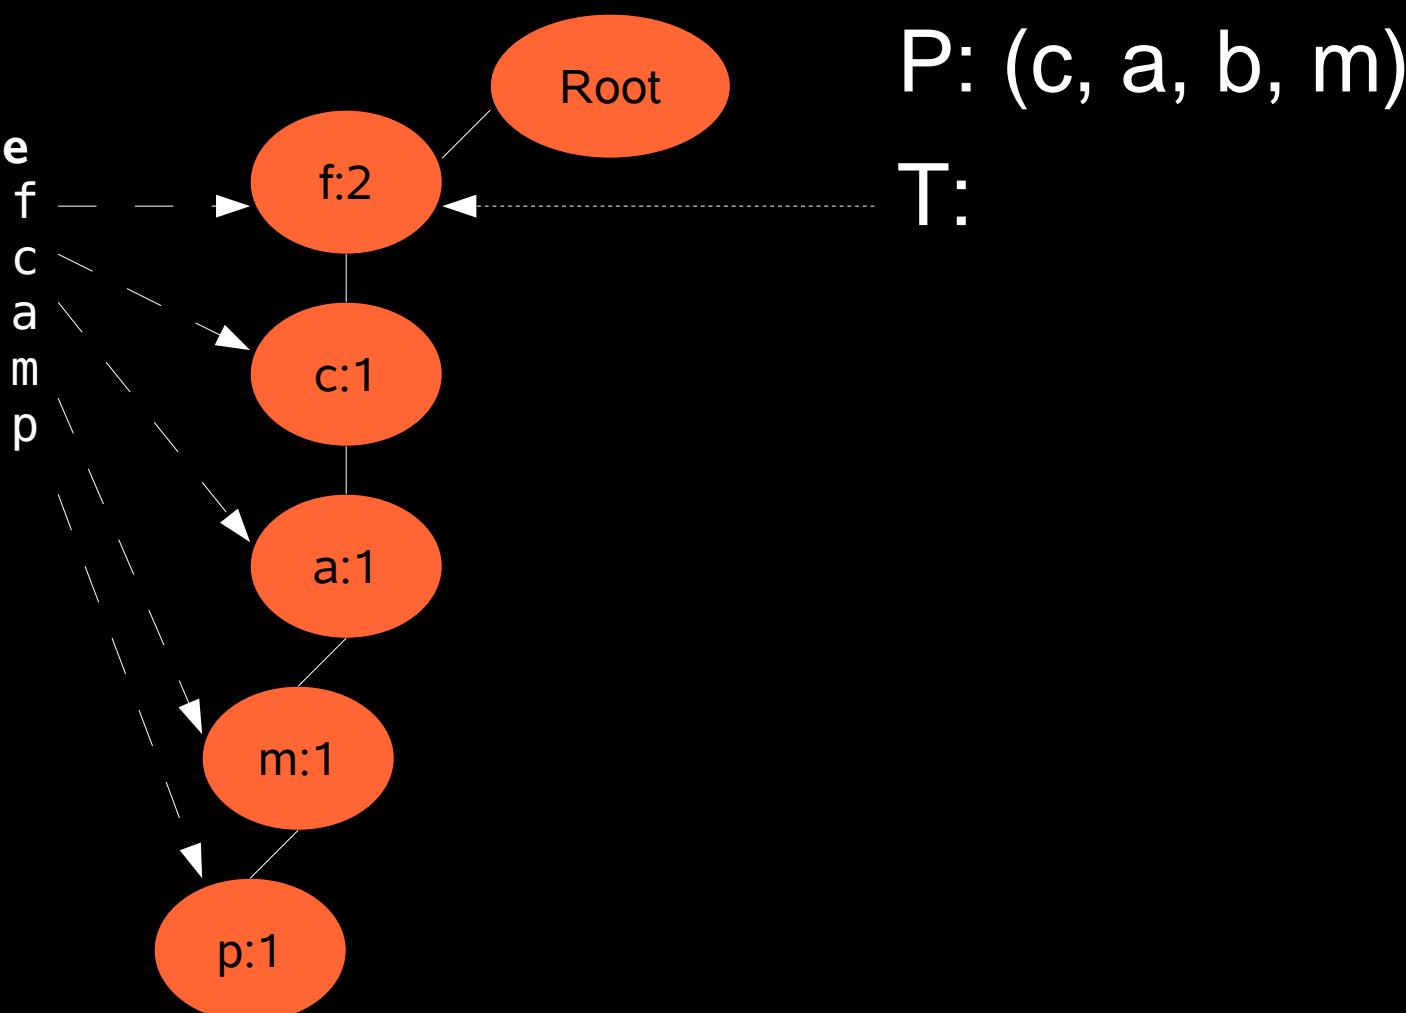

FP-Tree: Construction

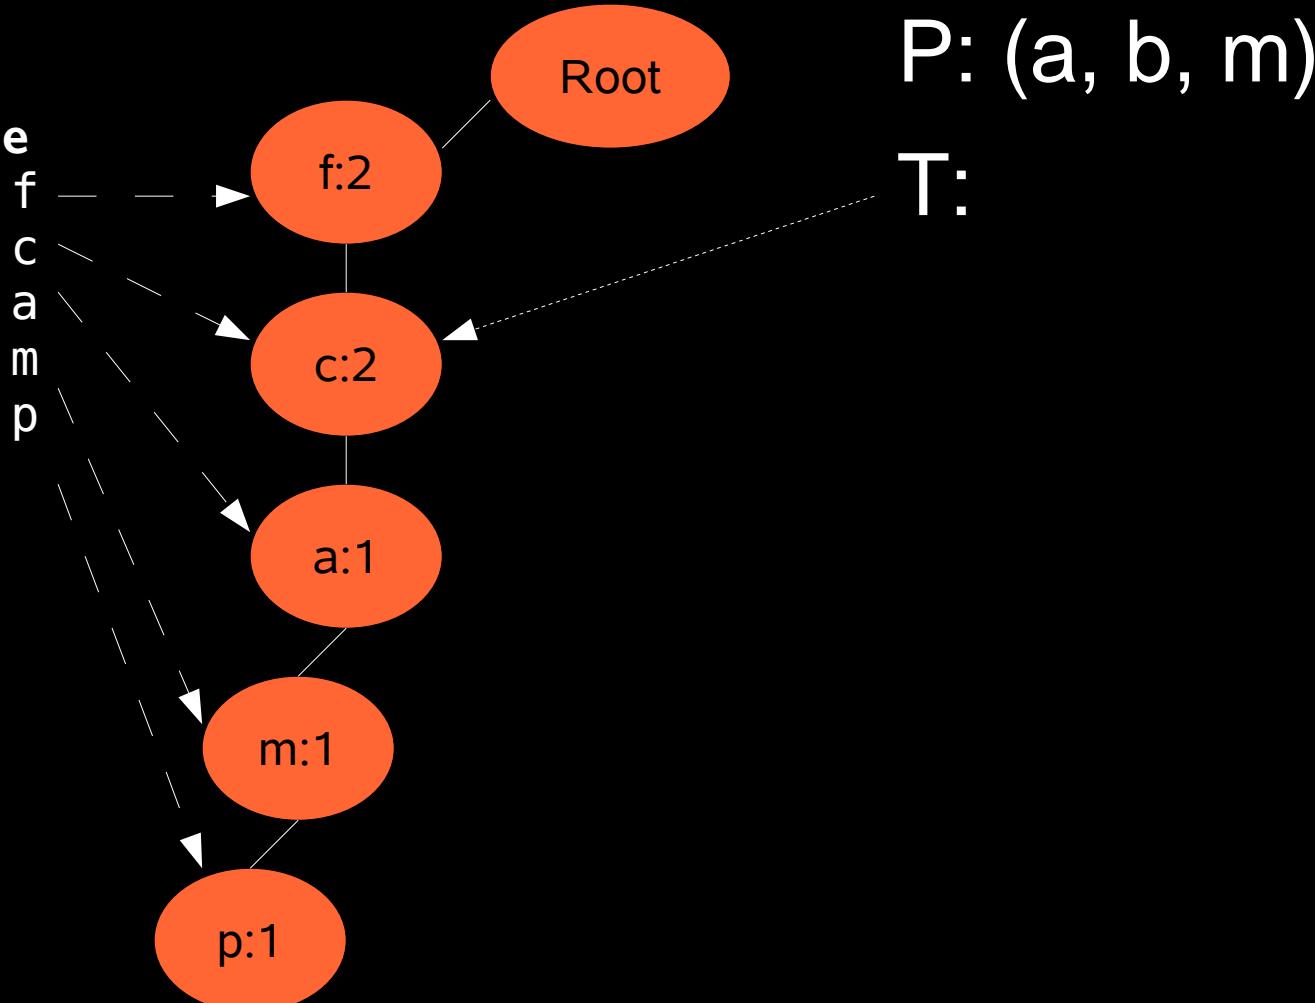

FP-Tree: Construction

Header table

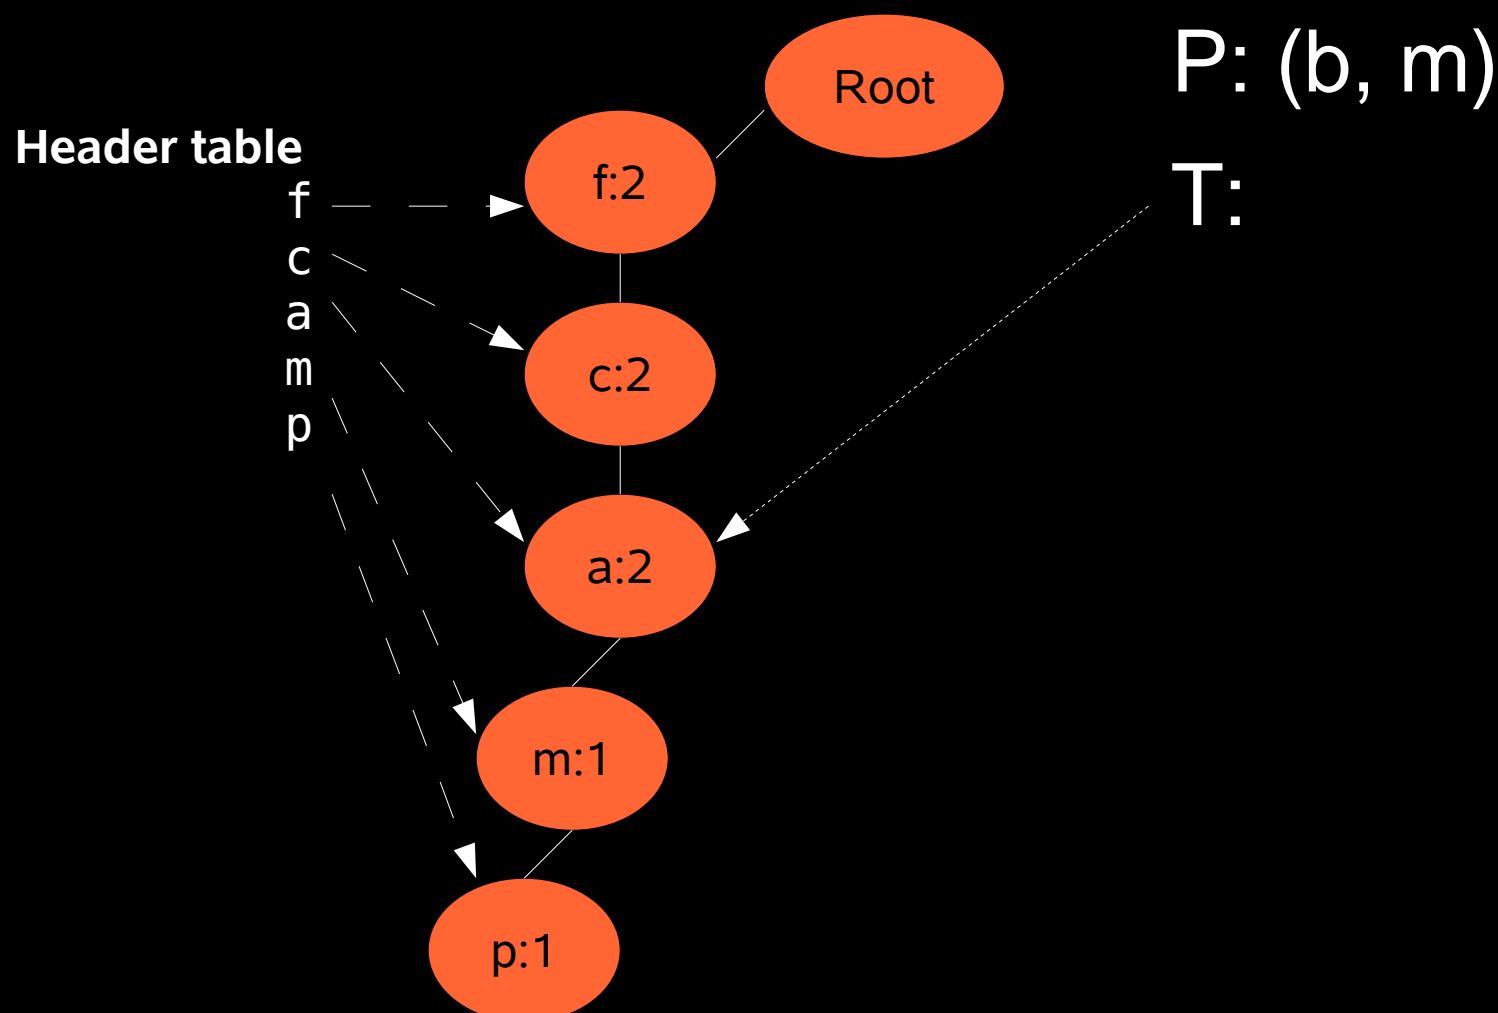

FP-Tree: Construction

Header table

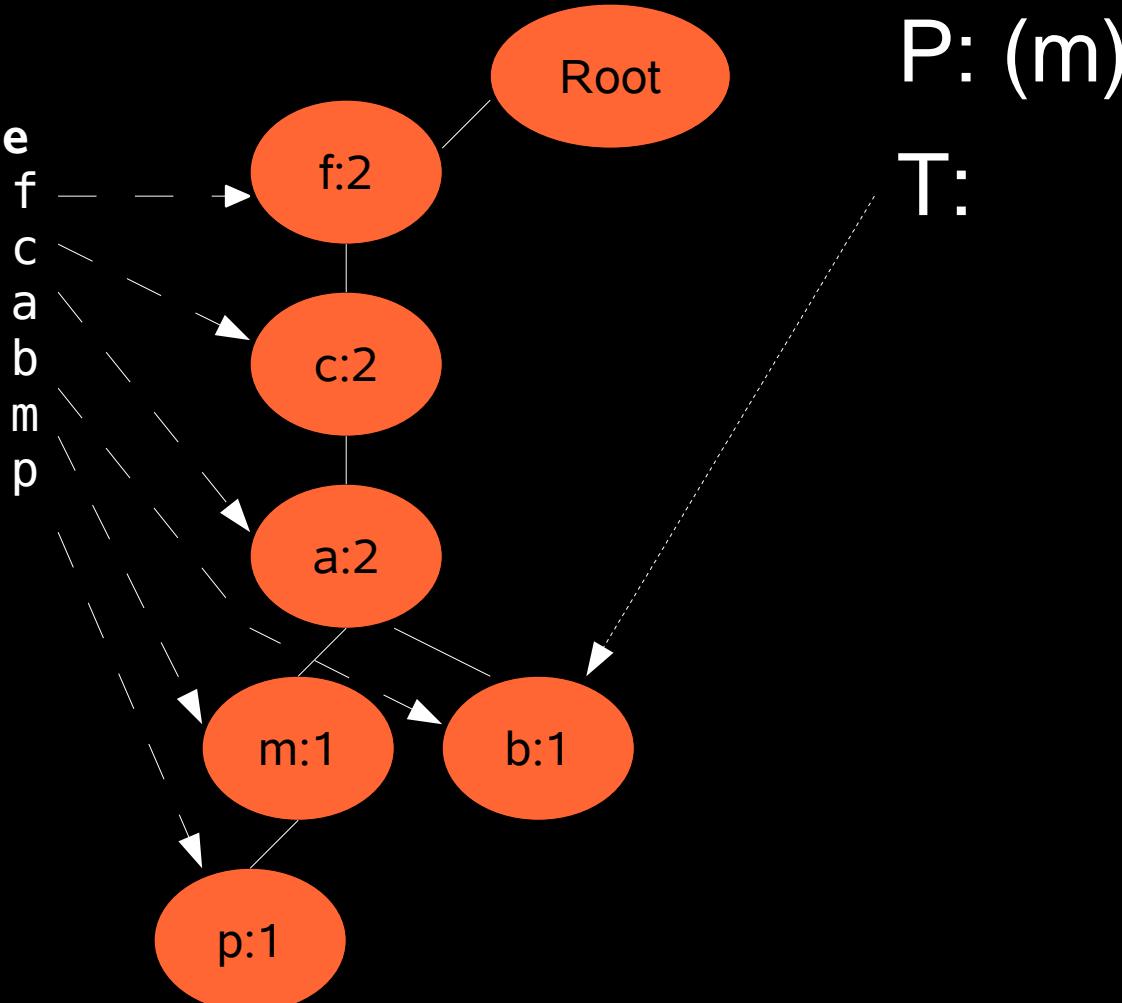

FP-Tree: Construction

T:

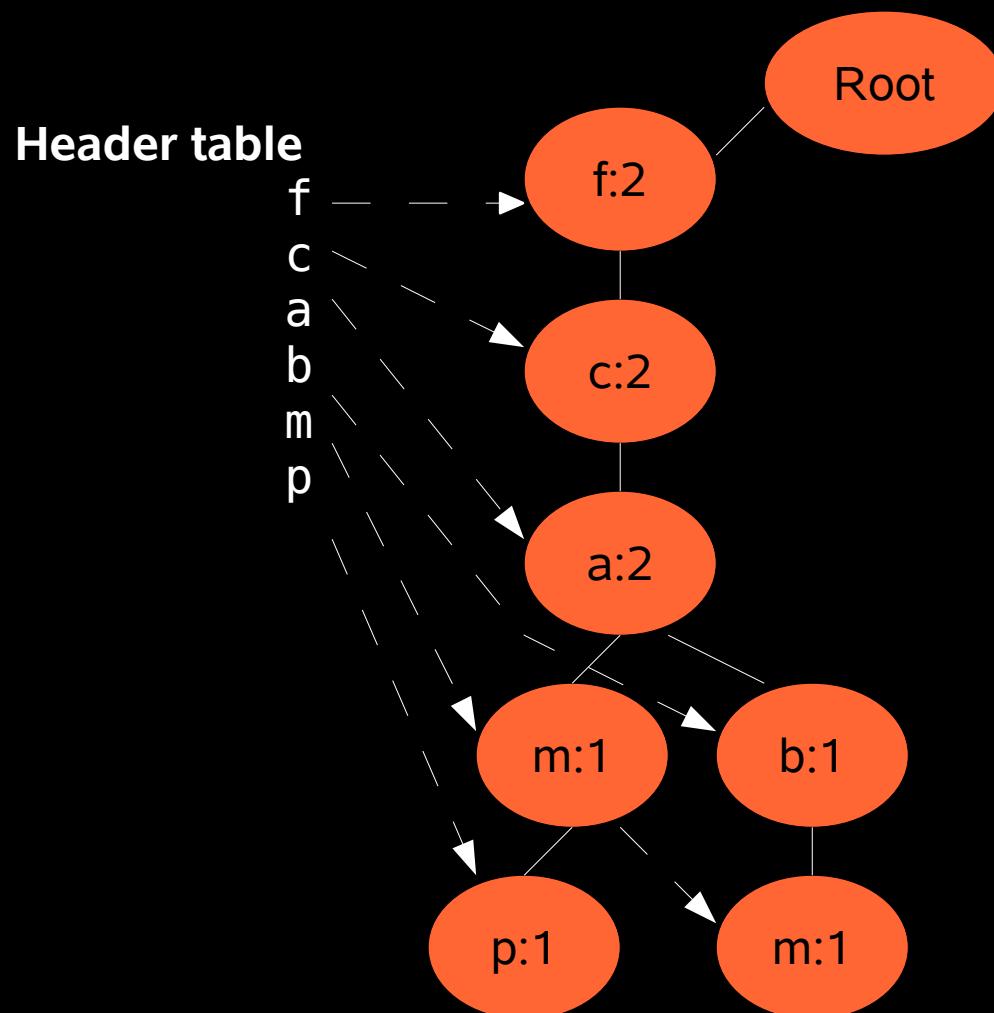

FP-Tree: Construction

Header table

FP-Tree: Construction

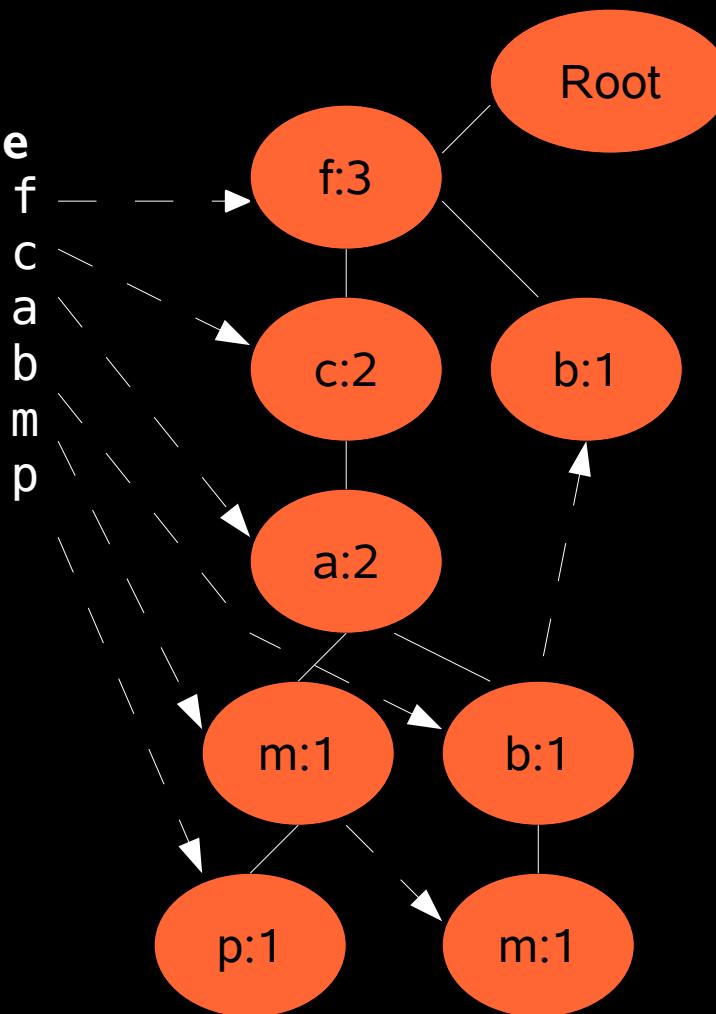

- Second insertion complete

FP-Tree: Construction

- After insertion of third transaction (f, b)

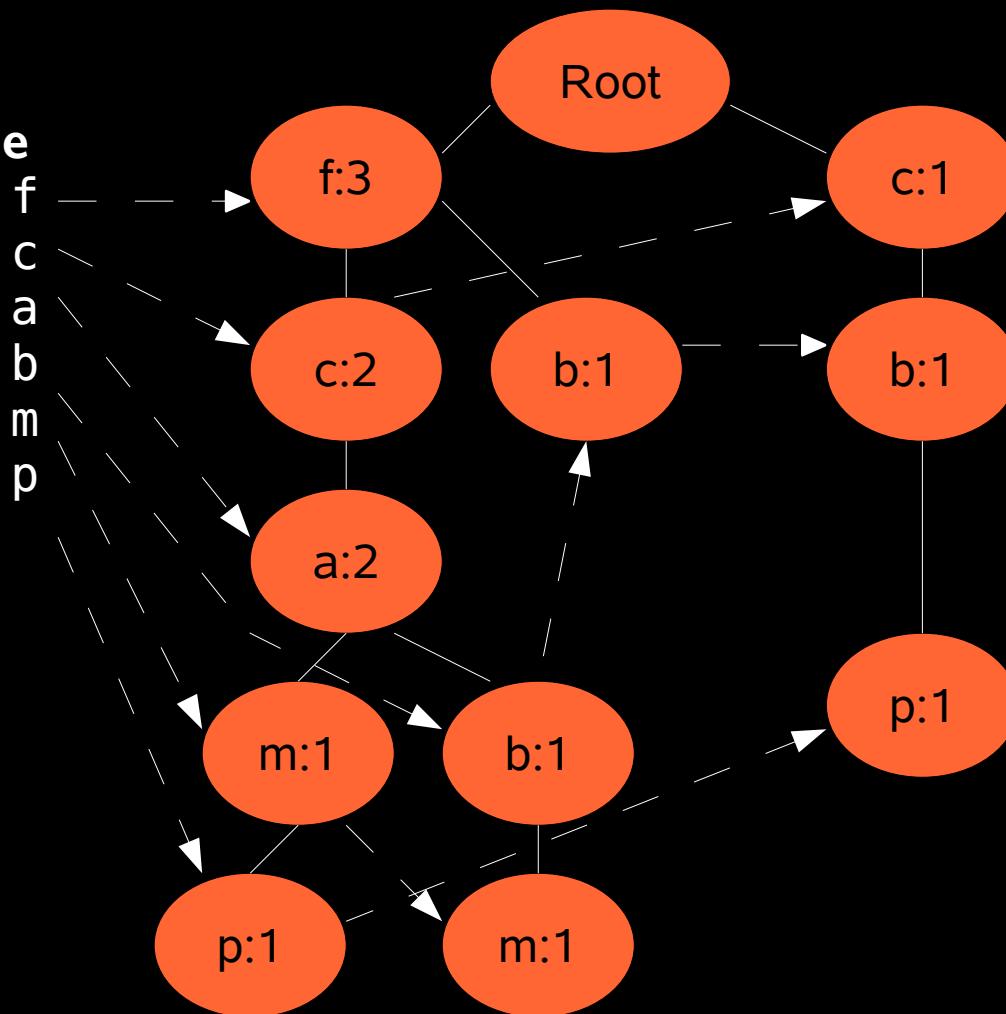

Header table

FP-Tree: Construction

- After insertion of fourth transaction (c, b, p)

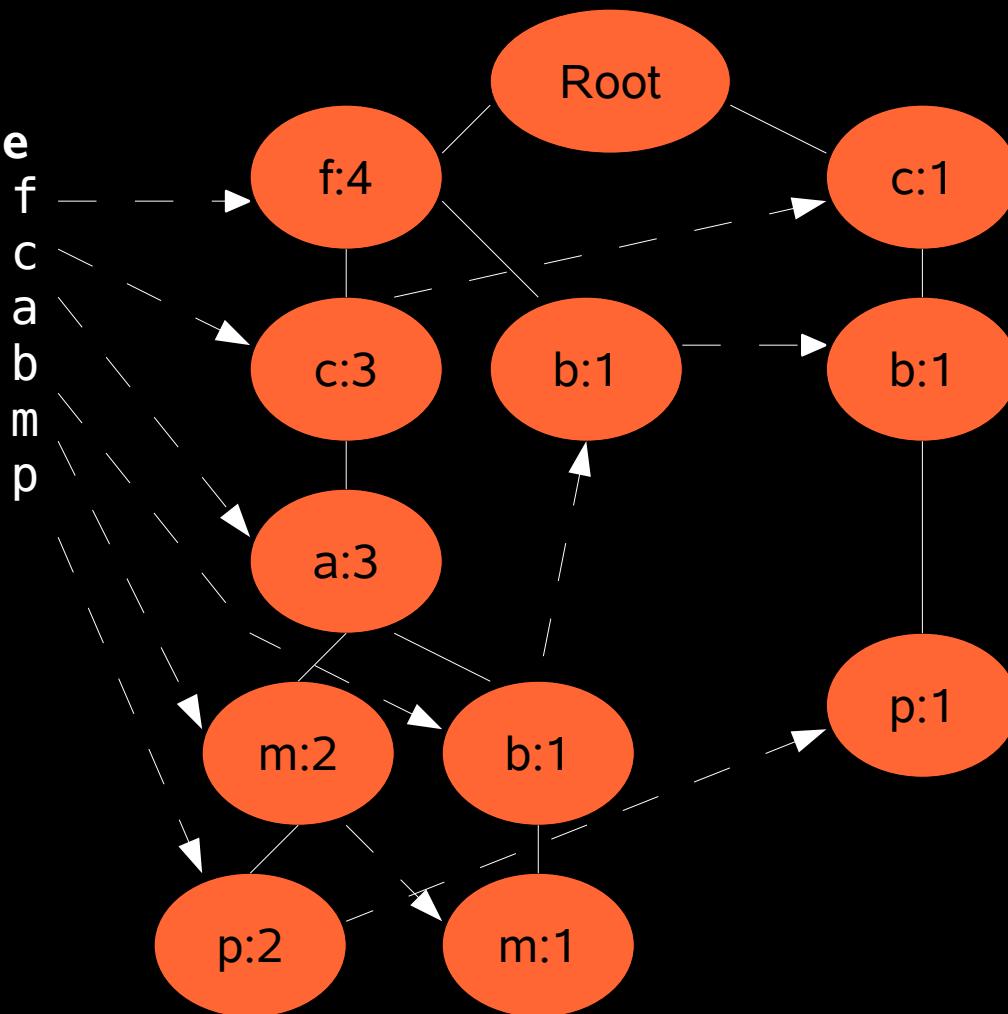

Header table

FP-Tree: Construction

- After insertion of fifth transaction (f, c, a, m, p)

Header table

FP-Tree: Properties

- The FP-Tree contains everything from the database we need to know for mining frequent patterns
- The size of the FP-tree is \leq Occurrence of frequent patterns in database

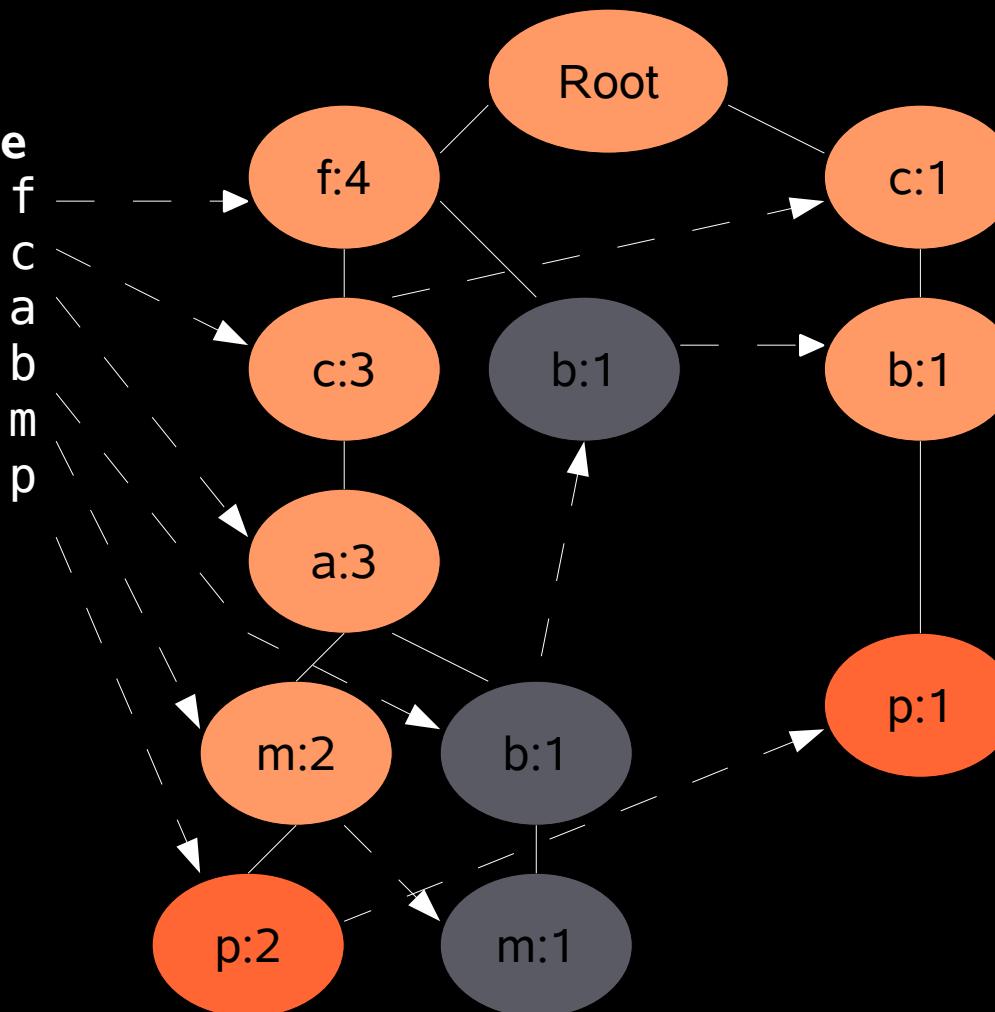

Mining Frequent Patterns

- How do we get find all frequent patterns from the FP-Tree?
 - Intuitively:
 - 1)Find all frequent patterns containing one of the items
 - 2)Then find all frequent patterns containing the next item but NOT containing the previous one
 - 3)Repeat 2) until we're out of items

Finding all patterns with 'p'

- Starting from the bottom of the header table

Header table

Generate (p:3)

'p' exists in
paths:

(f:4, c:3, a:3,
m:2, p:2) and
(c:1, b:1, p:1)
process these
further

Paths with 'p'

- We got (f:4, c:3, a:3, m:2, p:2) and (c:1, b:1, p:1)
- The transactions containing 'p' have p.count
- We get (f:2, c:2, a:2, m:2, p:2) and (c:1, b:1, p:1)
 - Since we know that 'p' is part of these we can drop 'p'

Conditional Pattern Base

- We get paths (p dropped):
 - (f:2, c:2, a:2, m:2) and (c:1, b:1)
- Called *conditional pattern base (CPB)*
 - Contains transactions in which 'p' occurs
 - To find all frequent patterns containing 'p' we need to find all frequent patterns in the CPB and add 'p' to them
 - We can do this by constructing a new FP-Tree for the CPB

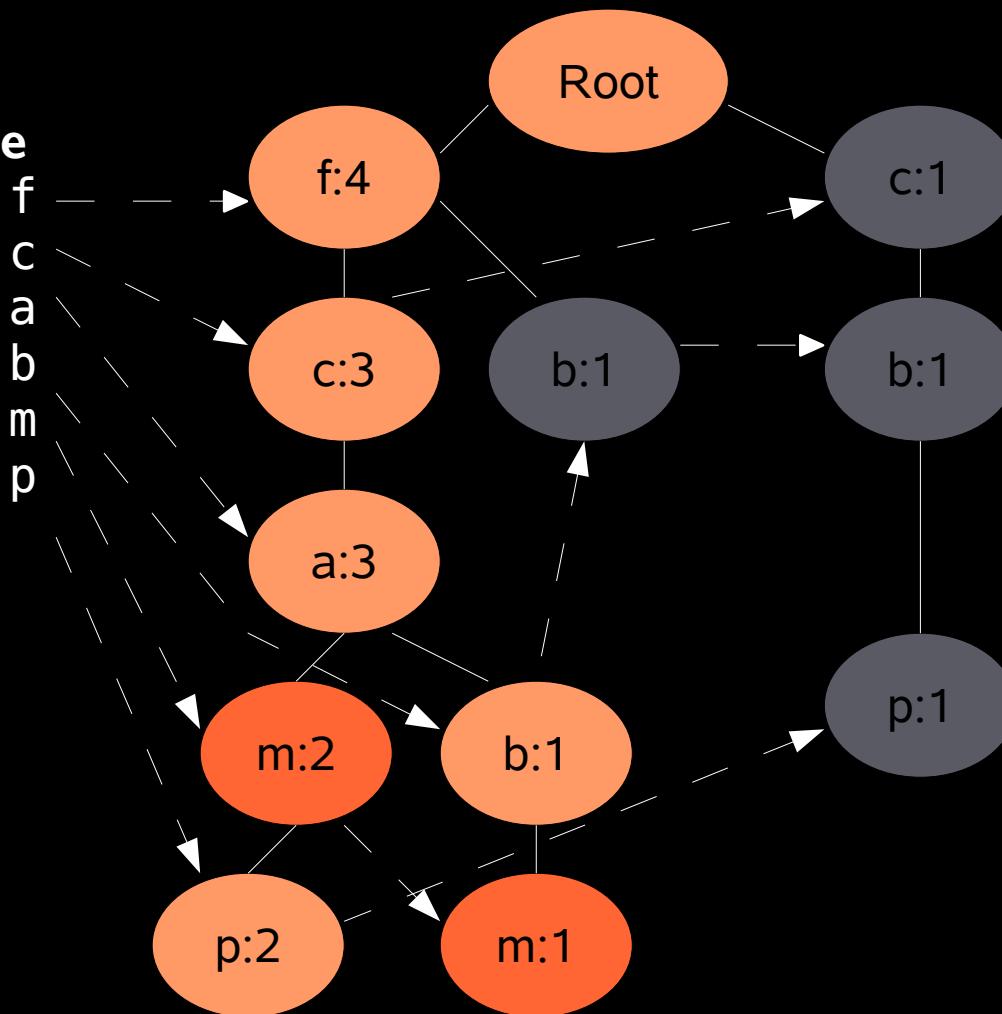

Finding all patterns with 'p'

- We again filter away all items < minimum support threshold
 - $(f:2, c:2, a:2, m:2), (c:1, b:1) \Rightarrow (c:3)$
- We generate (cp:3)
 - Support value is taken from the sub-tree
 - Frequent patterns thus far: (p:3, cp:3)

Patterns with 'm' but not 'p'

- Find 'm' from header table

Header table

Generate (m:3)

'm' exists in
paths:

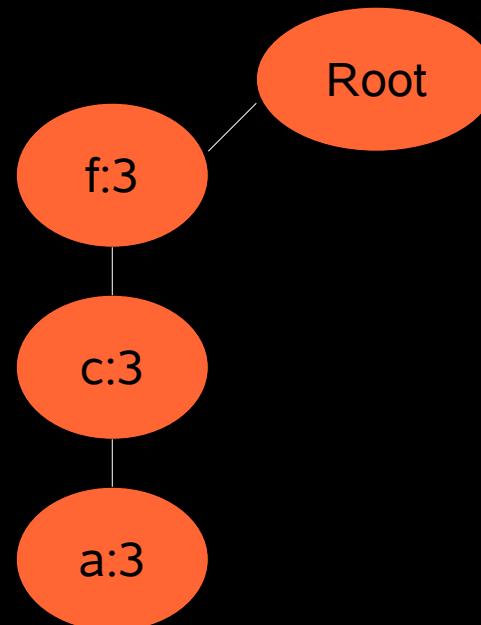

(f:4, c:3, a:3,
m:2, p:2) and
(f:4, c:3, a:3,
b:1, m:1)

Patterns with 'm' but not 'p'

- Conditional Pattern Base:
 - $(f:4, c:3, a:3, m:2, p:2) \rightarrow (f:2, c:2, a:2)$
 - $(f:4, c:3, a:3, b:1, m:1) \rightarrow (f:1, c:1, a:1, b:1)$
- Note: Only prefix considered
 - Systematic way of avoiding considering 'p'

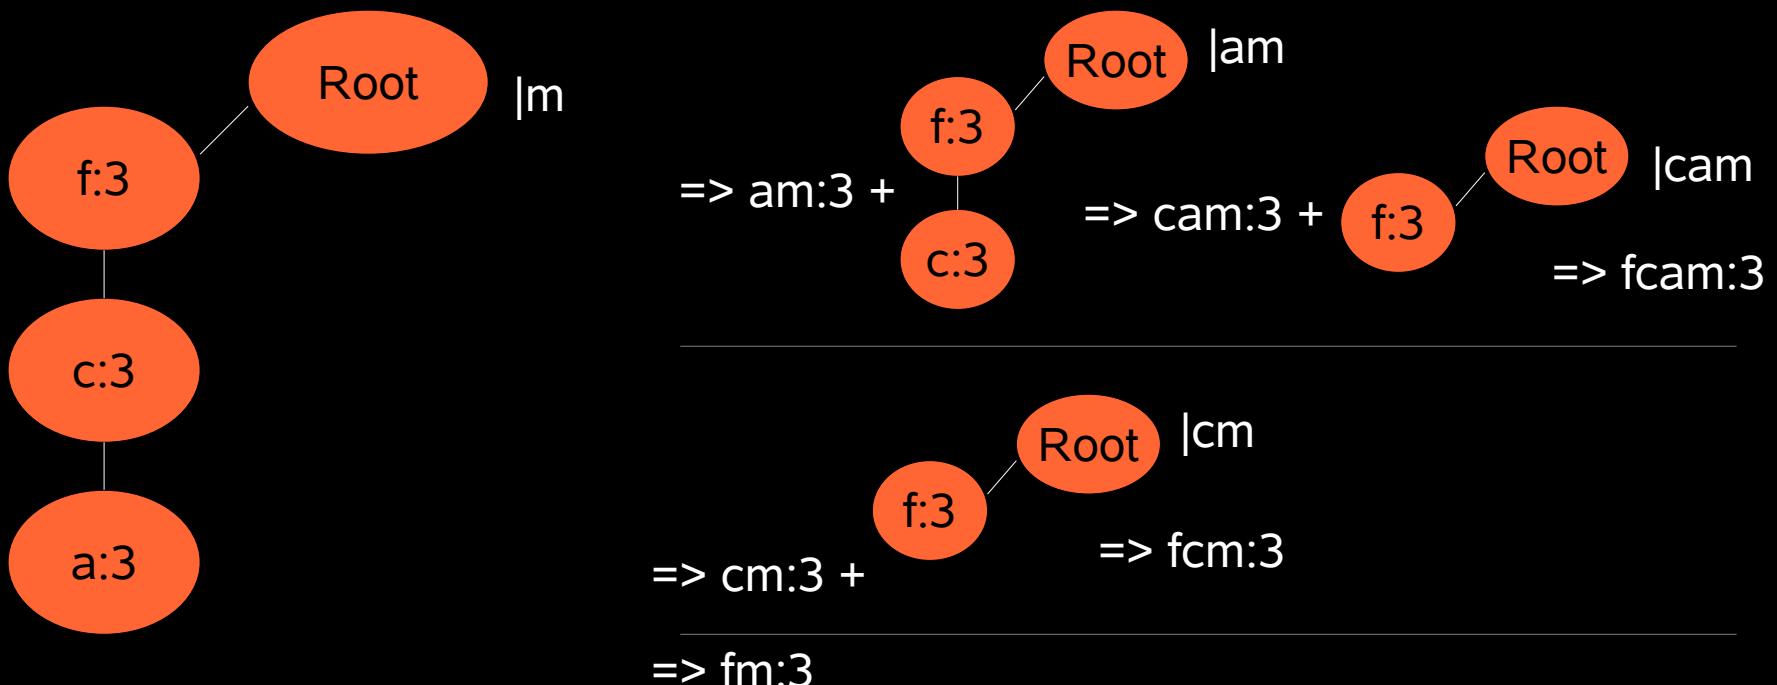

Patterns with 'm' but not 'p'

- Build FP-Tree from (f:2, c:2, a:2) and (f:1, c:1, a:1, b:1)
 - Initial filtering removes b:1
 - Resulting tree:

Conditional trees for 'm'

- Apply FP-Tree algorithm recursively to the new tree given 'm'
 - What this means is that to all frequent patterns found in this tree we add 'm'

Mining algorithm

FP-Growth(Tree , α)

for each(a_i in the header of Tree) do {

$\beta := a_i \cup \alpha$

generate(β with support = $a_i.\text{support}$)

construct β 's conditional base pattern
and β 's conditional FP-Tree Tree_β

if $\text{Tree}_\beta \neq \emptyset$

then call FP-growth(Tree_β , β)

Initially call:

FP-Growth(Tree , $null$)

Conclusions

- FP-Tree is an efficient algorithm for finding frequent patterns in transaction databases
- A compact tree structure is used
- Mining based on the tree structure is significantly more efficient than Apriori
